Question:

Shock causes:

Answer Choices:

A. Stagnant hypoxia

B. Anemic hypoxia

C. Hypoxic hypoxia

D. Histotoxic hypoxia

Reasoning + Answer:

<tool_call>

Shock leads to inadequate blood flow to tissues, resulting in reduced oxygen delivery to cells. This is primarily due to impaired perfusion, not a decrease in oxygen content of the blood or a problem with oxygen utilization.

In hypoxic hypoxia, there is a reduced partial pressure of oxygen in the alveoli or arterial blood, leading to low oxygen content in the blood. In shock, especially hypovolemic or cardiogenic shock, the blood flow to tissues is compromised, leading to tissue hypoxia due to poor perfusion âĢĶ this is known as **stagnant hypoxia**.

Stagnant hypoxia occurs when blood flow is reduced or absent, so oxygen cannot reach the tissues despite adequate oxygen content in the blood. This is the hallmark of shock, where the tissue is not receiving enough oxygen due to poor circulation, not because of low oxygen in the blood or impaired cellular utilization.

Anemic hypoxia occurs due to reduced hemoglobin (e.g., blood loss), not directly from shockâĢĻs perfusion failure.

Hypoxic hypoxia involves low oxygen tension in the lungs or blood.

Histotoxic hypoxia involves impaired oxygen utilization (e.g., cyanide poisoning), not typical in shock.

Therefore, the primary type of hypoxia seen in shock is **stagnant hypoxia**, as it reflects the impaired blood flow and tissue perfusion.

<answer>

A. Stagnant hypoxia

</answer>
