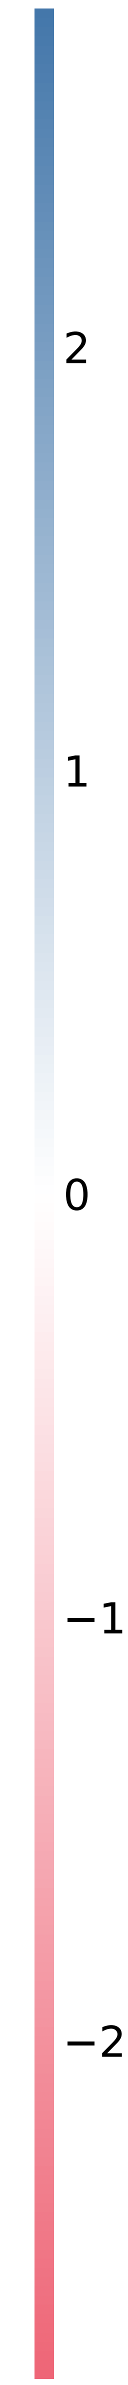
Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs $5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:



Let's break down the problem step by step.

1. **Identify the cost of the glasses:**
- The first glass costs $5.
- Every second glass costs 60% of $5, which is \(0.60 \times 5 = 3\) dollars.

2. **Calculate the total number of pairs of glasses:**
- Kylar wants to buy 16 glasses.
- The number of pairs of glasses is \(\frac{16}{2} = 8 \).

3. **Calculate the total cost for the pairs of glasses:**
- Each pair consists of one glass at $5 and one glass at $3.
- The cost for one pair is \(5 + 3 = 8\) dollars.
- Therefore, the total cost for 8 pairs is \(8 \times 8 = 64\) dollars.

4. **Calculate the total cost for the remaining single glasses:**
- Since 16 glasses form 8 pairs, there are no single glasses left.
- So, the total cost for the remaining single glasses is $0.

5. **Calculate the final total cost:**
- The total cost for the glasses is the sum of the cost of the pairs and the cost of the remaining single glasses.
- The total cost is \(64 + 0 = 64\) dollars.

<think>
- We determined that each pair of glasses costs $8.
- There are 8 pairs of glasses.
- Therefore, the total cost for the pairs is 8 * 8 = 64 dollars.
- There are no single glasses left, so the total cost for the remaining single glasses is 0 dollars.
- The final total cost is 64 + 0 = 64 dollars.
</think>

<answer>64</answer>
