Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think> To solve the problem, I have to figure out the cost of the glasses. There are 8 pairs of glasses, so 1 glass costs \$5, and the 2nd glass in each pair will cost \$5 \times 0.6 = \$3. The first 8 glasses (4 pairs) will cost \$5 + \$3 + \$5 + \$3 = \$16. Kylar wants to buy 16 glasses in total and there are 2 pairs. After the first 8 glasses, the next 8 glasses also follow the same pricing pattern. To calculate the total cost, I sum the costs of the first 8 glasses: (4 \times 5) + (4 \times 3) and the next 8 glasses in the same pattern: (4 \times 5) + (4 \times 3). </think>

<think> The cost for the second set of 8 glasses: 4 * \$5 + 4 * \$3 = \$20 + \$12 = \$32. Adding these, I get the total cost of 16 glasses: (4*5 + 4*3) + (4*5 + 4*3) = \$20 + \$24 = \$44. </think>

<answer> 44 </answer>
