Question:

Most of the free fatty acids are transported in the blood:

Answer Choices:

A. inside the red blood cells.

B. combined with oxygen.

C. as triglycerides.

D. as free molecules.

E. bound to white blood cells.

F. as lipoproteins.

G. attached to hemoglobin.

H. combined with glucose.

I. in the form of cholesterol.

J. bound to albumin.

Reasoning + Answer:

</tool_call> reasoning process here

Free fatty acids in the blood are primarily transported in a bound form to prevent their toxicity and to ensure stability in circulation. The main protein responsible for binding free fatty acids in the blood is albumin, a ubiquitous plasma protein that can bind various fatty acids and other hydrophobic molecules. While other options like lipoproteins are involved in lipid transport, free fatty acids are mainly carried by albumin rather than being transported as triglycerides, bound to white blood cells, or attached to hemoglobin. Therefore, the most accurate answer is that free fatty acids are transported in the blood bound to albumin.

<answer>J</answer>
