Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs $5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>
First, let's figure out how much Kylar will spend on 16 glasses that follow the discounted pricing pattern; second glass 60% off the first one's price is $5 multiplied by 0.60.
The total cost is calculated as the sum of the full-price glasses and the discounted glasses in pairs: that implies if Kylar buys in pairs (e.g., 1 full price and 1 discounted, or 2 discounted ones).
Divide the total number of glasses by two (eight pairs) to determine the total cost of a set of 2 glasses, but remember not all cases can neatly divide into pairs if he buys odd numbers. Apply the discount only on the second of each pair.
Thus, each pair would have first glass: 5 and second glass 5 * 0.6 = 3, total pair cost is 5 + 3.
Cost for eight pairs is 8 * (5 + 3). Because the scenario here adheres to pairs, we can easily calculate.
