

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

Let's break down the pricing and calculate the cost step by step.

<think>

- The first glass costs \$5.

- Every second glass is 60% of the regular price, which means it costs $(5 \times 0.60 = 3)$ dollars.

To determine how many glasses are "first" and how many are "second":

- If Kylar buys 16 glasses, we can consider the sequence as: 1st, 2nd, 1st, 2nd, ... and so on.

- In a sequence of 16, every second glass is at the 2nd, 4th, 6th, 8th, 10th, 12th, 14th, and 16th positions.

- Therefore, he will buy 8 glasses at \$5 and 8 glasses at \$3.

Now, let's calculate the total cost for the first and second glasses:

- Total cost for the first 8 glasses: $(8 \times 5 = 40)$ dollars.

- Total cost for the second 8 glasses: $(8 \times 3 = 24)$ dollars.

Adding these together gives us the total cost:

- $(40 + 24 = 64)$ dollars.

So, Kylar needs to pay \$64 for 16 glasses.

</think>

<answer>

64

</answer>
