

Question:

Structure held by forceps is seen in Answer Choices: A. Stomach B. Appendix C. Colon D. Duodenum

Reasoning + Answer:

<think>The structure that is held by forceps is typically related to surgical procedures, where forceps are used to grasp and hold tissue or organs in place. In the context of gastrointestinal tract, the structure that is commonly held by forceps is the appendix. This is because the appendix is a small, narrow organ that needs to be grasped and ligated during appendectomies. The other options, such as the stomach, colon, and duodenum, are larger organs that may require different types of instruments or techniques for grasping and handling. </think><answer> B . Appendix </answer>
