

Question:

A plague infects ten people. Every day, each infected person infects six others. How many people are infected after three days?

Reasoning + Answer:

<think>There are initially 10 people infected. Each of them infects six others, so in a day, $10 * 6 = 60$ new people become infected. So after the first day, the total is 10 (originals) + $60 = 70$ people. The pattern of $10 * 6$ continues, so the second day brings $70 * 6 = 420$ new people. The new total is 70 (previous) + $420 = 490$. The third day brings $490 * 6 = 2940$ new people. The total is then 490 (previous) + $2940 = 3430$ people infected. The answer is 3430 people. </think><answer>3430</answer>
