

Question:

Conor lives near a beach and loves going there every day to have fun. On a particular week, he found 50 people at the beach on the first day. The next day, 20 more people were present at the beach than on the first day, and on the third day, the total number of people increased to twice the number that were there on the second day. If Conor saw an average of 60 people each day the rest of the week, calculate the total number of people Conor saw at the beach that week.

Reasoning + Answer:

<think>He found 50 people on the first day. The next day, 20 more people were present so 50 + 20 = 70 people. On the third day the total number of people increased to twice the number that were there on the second day so 70 x 2 = 140 people. He saw an average of 60 people each day the rest of the week so 60 x 4 = 240 people. The total number of people he saw that week is 50 + 70 + 140 + 240 = 460 people. </think><answer>460</answer>
