

Question:

A 7-year-old girl comes in to the emergency department with her mother for swelling of her left periorbital region. Yesterday morning she woke up with a painful, warm, soft lump on her left eyelid. Eye movement does not worsen the pain. Physical examination shows redness and swelling of the upper left eyelid, involving the hair follicles. Upon palpation, the swelling drains purulent fluid. Which of the following is the most likely diagnosis? Answer Choices: A. Hordeolum B. Blepharitis C. Xanthelasma D. Chalazion

Reasoning + Answer:

<think>Given the presence of a painful, warm lump, along with purulent drainage, indicative signs pointing towards an infection, this is most likely a Hordeolum. The other options, Blepharitis, Xanthelasma, and Chalazion, do not typically present with purulent drainage. Therefore, the most likely diagnosis is Hordeolum.</think><answer>Hordeolum</answer>
