

Question:

An 11-year-old girl is brought to the physician by her parents because of a mildly pruritic rash on her trunk and extremities for 2 days. One week ago, she developed a low-grade fever, rhinorrhea, and headache, followed by a facial rash 4 days later. The facial rash did not involve the perioral skin. Her temperature is 37.4°C (99.3°F). A photograph of the rash on her lower arms is shown. Which of the following is the most likely diagnosis? Answer Choices: A. Rubella B. Erythema infectiosum C. Exanthem subitum D. Scarlet fever

Reasoning + Answer:

<think>The patient had a pruritic rash for 2 days. She had a low-grade fever, rhinorrhea, and headache. The facial rash appeared 4 days after the onset of other symptoms. A photograph was provided. Rubella, Erythema infectiosum, Exanthem subitum, and Scarlet fever were possible diagnoses. </think><answer>Erythema infectiosum</answer>
