

Question:

Which type of articulators permit horizontal as well as vertical motion, but do not orient the motion to the TMJ via facebow transfer?

Answer Choices:

- A. Class I
- B. Class II
- C. Class III
- D. Class IV

Reasoning + Answer:

mobx

To determine which type of articulator allows horizontal and vertical motion without orienting motion to the TMJ via facebow transfer, we must understand the classification of dental articulators.

Class I articulators :

- Allow both vertical and horizontal motion .
- Motion is oriented to the TMJ using facebow transfer .
- Therefore , they do orient motion via facebow transfer ~~~ not correct .

Class II articulators :

- Allow horizontal and vertical motion .
- Motion is oriented using a different method (e.g ., direct alignment or indirect), but typically still involves some form of facebow transfer .
- Still relies on facebow transfer for TMJ orientation ~~~ not correct .

Class III articulators :

- Allow horizontal and vertical motion .
- Do NOT use facebow transfer to orient the motion .
- The TMJ motion is not transferred via facebow ; instead , the articulator is designed to simulate TMJ motion independently .
- This is the type that permits horizontal and vertical motion without facebow orientation .

Class IV articulators :

- Generally used for research or specific applications .
- Not typically defined for horizontal / vertical motion without facebow transfer .

The key distinction is that Class III articulators allow both horizontal and vertical motion but do not require or use facebow transfer to orient the TMJ motion .

Therefore , the correct answer is Class III .

< answer >

C . Class III

</ answer >
