

Question:
Coical representation of body in the cerebrum is
Answer Choices:
A. Horizontal
B. Veical
C. Tandem
D. Oblique

Reasoning + Answer:

<tool_call>

The cortical representation of the body in the cerebrum refers to the somatosensory cortex, specifically the somatotopic organization known as the somatosensory homunculus. This map is not horizontal, vertical, or oblique in a simple anatomical sense. Instead, it is organized in a way that reflects the relative importance and surface area of body parts. The homunculus is arranged such that areas with more complex sensory input (like the face and hands) occupy larger cortical areas, while less sensitive regions (like the back) occupy smaller areas.

The key feature of this organization is that it is **not** strictly vertical or horizontal. The term "tandem" is not a standard anatomical term used for body representation in the cortex. The correct description of the organization is best described as a **somatotopic arrangement**, which is often visualized as a distorted, non-linear map.

However, among the given options, the term "tandem" is not standard. But if we interpret the options in the context of known neuroanatomical descriptions, the body representation is often described as being **"in a distorted, non-linear fashion"** and sometimes referred to in terms of a **"tandem" or "ladder-like"** arrangement in some older texts, though this is not the standard term.

Given that the correct anatomical term is not directly listed, and considering that the representation is not strictly horizontal, vertical, or oblique and that "tandem" is used in some outdated or descriptive contexts to refer to the way body parts are arranged in sequence, it is possible that "tandem" is intended to describe the sequential, paired arrangement of body parts in the somatosensory cortex.

None of the options are perfect, but among the choices, "tandem" is the closest to describing the sequential, paired, body-part organization.

<answer>

C. Tandem

</answer>
