

Question:
Which type of articulators permit horizontal as well as vertical motion, but do not orient the motion to the TMJ via facebow transfer?

- Answer Choices:
- A. Class I
 - B. Class II
 - C. Class III
 - D. Class IV

Reasoning + Answer:

<tool_call>

To determine which type of articulator allows horizontal and vertical motion but does not orient motion to the TMJ via face bow transfer , we need to understand the classification of dental articulators .

Articulators are categorized into Classes I through IV based on how they simulate the movement of the temporomandibular joint (TMJ).

- Class I articulators : Allow vertical and horizontal movements and use face bow transfer to orient the motion to the TMJ . They are the most accurate in simulating TMJ motion .
- Class II articulators : Allow horizontal and vertical movements but do not use face bow transfer . The motion is not oriented to the TMJ based on the patient's TMJ anatomy . This is the key point .
- Class III and IV articulators : Are more complex and often involve additional features like rotational or compound movements , and typically use face bow transfer or other methods to orient the motion .

The question specifically asks for articulators that allow both horizontal and vertical motion but do NOT orient the motion to the TMJ via face bow transfer . This is a defining characteristic of Class II articulators .

Class II articulators are designed to provide both horizontal and vertical movement , but they do not use face bow transfer to orient the motion to the TMJ . Instead , they rely on fixed or arbitrary positioning , which makes them less accurate but simpler in design .

Therefore , the correct answer is Class II .

< answer >

B . Class II
