

**Question:**  
An 85 years old man underwent transurethral resection of prostate. A histological examination of his specimen showed T1a stage of adenocarcinoma: management will be:

- Answer Choices:
- A. Endocrine therapy
  - B. Radical surgery
  - C. Hormone therapy
  - D. No further treatment

**Reasoning + Answer:**

<think>

1. The patient is an 85-year-old man who has undergone transurethral resection of the prostate (TURP).

2. The histological examination of the specimen revealed T1a stage adenocarcinoma.

3. T1a stage adenocarcinoma of the prostate is considered a very early stage of prostate cancer, indicating that the tumor is confined to the prostate gland and is small.

4. For T1a stage adenocarcinoma, the risk of metastasis is very low, and the tumor is often considered to be clinically insignificant.

5. Given the patient's age (85 years), the likelihood of successful surgical intervention is low due to potential comorbidities and the patient's overall health status.

6. Hormone therapy or endocrine therapy may be considered for more advanced stages of prostate cancer, but for T1a stage, these treatments are not typically indicated.

7. The most appropriate management for a T1a stage adenocarcinoma in this context would be to avoid further active treatment, given the low risk of progression and the patient's age.

Conclusion: The most appropriate management for a T1a stage adenocarcinoma in this elderly patient would be no further treatment.

</think>

<answer>

D. No further treatment
