

Question:

An 85 years old man underwent transurethral resection of prostate. A histological examination of his specimen showed T1a stage of adenocarcinoma: management will be:

Answer Choices:

- A. Endocrine therapy
- B. Radical surgery
- C. Hormone therapy
- D. No further treatment

Reasoning + Answer:

<think>

- The patient is an 85-year-old man who underwent a transurethral resection of the prostate.
- The histological examination revealed T1a stage adenocarcinoma.
- T1a stage indicates a small, localized tumor that is confined to the prostate gland and has not invaded the capsule or spread to lymph nodes or other distant sites.
- For T1a stage adenocarcinoma, the standard management is usually active surveillance rather than radical surgery or endocrine therapy, especially in elderly patients.
- Radical surgery is typically reserved for more advanced stages or when the cancer is larger or more aggressive.
- Endocrine therapy is used for more advanced stages of prostate cancer, particularly when the cancer is hormone-sensitive.
- No further treatment is not recommended for T1a stage adenocarcinoma as it may progress to more aggressive forms.
