

Question:

Shock causes:

Answer Choices:

- A. Stagnant hypoxia
- B. Anemic hypoxia
- C. Hypoxic hypoxia
- D. Histotoxic hypoxia

Reasoning + Answer:

<think>

- Shock is a state where there is inadequate perfusion of tissues and organs , leading to cellular hypoxia and metabolic acidosis .
- Hypoxic hypoxia is defined by a decreased availability of oxygen at the tissue level despite normal hemoglobin levels and normal pulmonary gas exchange . This is the most common type of hypoxia in shock , as the perfusion of tissues is impaired .
- Stagnant hypoxia occurs when blood flow is reduced or stopped , leading to inadequate tissue perfusion . However , this is more specifically related to circulation rather than oxygen availability .
- Anemic hypoxia occurs when there is a reduction in the number of red blood cells or hemoglobin , thereby reducing oxygen -c arry ing capacity . This is not directly related to shock .
- Histotoxic hypoxia involves the inability of tissues to use oxygen despite normal oxygen availability . This is not a primary mechanism in shock .

</think>

<answer>

C . Hypoxic hypoxia

</answer>
