

Question:
Reed sternberg cells are found in-
Answer Choices:
A. Hodkin's disease
B. Sickle cell anaemia
C. Thalassemia
D. CML

Reasoning + Answer:

<think>
Reed-Sternberg (RS) cells are characteristic of certain types of lymphomas, particularly Hodgkin's lymphoma. RS cells are large, multinucleated cells that can be identified under microscopic examination of lymph node biopsies. They are not associated with sickle cell anemia, thalassemia, or chronic myeloid leukemia (CML), which are all hematological disorders but do not involve the presence of RS cells.

- Reed-Sternberg cells are specific to Hodgkin's lymphoma.
- Sickle cell anemia and thalassemia are hemoglobinopathies that affect red blood cells.
- Chronic myeloid leukemia involves the accumulation of myeloblasts and myeloid cells but does not feature Reed-Sternberg cells.

Given the options provided, Reed-Sternberg cells are exclusively associated with Hodgkin's disease.
