

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>

To find the total cost , I need to first determine the cost of each type of glass . The first glass costs \$ 5 , and the second glass costs 60 % of \$ 5 , which is $0.6 * 5 = \$ 3$.

Now , I need to find the total number of each type of glass Kylar wants to buy . Since Kylar wants to buy 16 glasses in total , and the price of the first glass is the same as the second glass , I can assume that he wants to buy 8 of each type of glass .

Now , I can calculate the total cost of the first glasses . The cost of 8 first glasses is $8 * 5 = 40$ dollars .

Next , I need to calculate the total cost of the second glasses . The cost of 8 second glasses is $8 * 3 = 24$ dollars .

To find the total cost , I need to add the cost of the first and second glasses . Total cost = cost of first glasses + cost of second glasses = $40 + 24 = 64$ dollars .

</think>< answer> 64 </answer>
