

Question:

A baby is born after the 32nd gestational week by cesarean delivery. The mother suffered from gestational diabetes; however, she had no other pregnancy-related diseases and was otherwise healthy. The baby has a blood pressure of 100/58 mm Hg, heart rate of 104/min, and oxygen saturation of 88%. The child has tachypnea, subcostal and intercostal retractions, nasal flaring, and cyanosis. The cyanosis is responding well to initial administration of oxygen. The nasogastric tube was positioned without problems. Which of the following is the most likely diagnosis?

Answer Choices:

- A. Neonatal respiratory distress syndrome (NRDS)
- B. Tracheoesophageal fistula
- C. Pneumonia
- D. Congenital heart anomaly with right-to-left shunt

Reasoning + Answer:

<think> The baby has tachypnea, subcostal and intercostal retractions, nasal flaring, and cyanosis, and the cyanosis is responding well to oxygen. These symptoms are consistent with respiratory distress, and the fact that the baby was born by cesarean delivery and has a low oxygen saturation suggests a respiratory issue. Pneumonia is a common respiratory condition in newborns, especially if they are already in a compromised state. </think><answer>Pneumonia</answer>
