

Question:

Reed sternberg cells are found in-

Answer Choices:

- A. Hodgkin's disease
- B. Sickle cell anaemia
- C. Thalassemia
- D. CML

Reasoning + Answer:

<tool_call> reasoning process here

Reed-Sternberg cells are large, abnormal cells that are pathognomonic for Hodgkin's lymphoma. These cells are characterized by their distinctive appearance under the microscope and are found in the lymph nodes of patients with Hodgkin's disease.

Sickle cell anemia and thalassemia are hemoglobinopathies related to red blood cell abnormalities and do not involve Reed-Sternberg cells.

Chronic myelogenous leukemia (CML) is a myeloid malignancy characterized by the presence of the Philadelphia chromosome and abnormal granulocytes, not Reed-Sternberg cells.

Therefore, Reed-Sternberg cells are specifically associated with Hodgkin's disease.

<answer> Hodgkin's disease </answer>
