

Question:

A baby is born after the 32nd gestational week by cesarean delivery. The mother suffered from gestational diabetes; however, she had no other pregnancy-related diseases and was otherwise healthy. The baby has a blood pressure of 100/58 mm Hg, heart rate of 104/min, and oxygen saturation of 88%. The child has tachypnea, subcostal and intercostal retractions, nasal flaring, and cyanosis. The cyanosis is responding well to initial administration of oxygen. The nasogastric tube was positioned without problems. Which of the following is the most likely diagnosis?

Answer Choices:

- A. Neonatal respiratory distress syndrome (NRDS)
- B. Tracheoesophageal fistula
- C. Pneumonia
- D. Congenital heart anomaly with right-to-left shunt

Reasoning + Answer:

<think>

- The baby has signs of respiratory distress such as tachypnea , retractions , nasal flaring , and cyanosis .

- The mother had gestational diabetes , but this does not directly indicate a specific diagnosis .

- NRDS is more common in preterm infants , but it can occur in term infants as well .

- Tracheoesophageal fistula would present with feeding difficulties and aspiration , but the nasogastric tube was placed without issues .

- Pneumonia can cause respiratory distress , but the absence of fever and the presence of oxygen response are less indicative of pneumonia .

- The most likely diagnosis given the signs of respiratory distress and the mother's history of gestational diabetes (which can affect fetal lung development) is NRDS .

- However , the presence of cyanosis and respiratory distress in a term infant is more commonly associated with a congenital heart anomaly with a right-to-left shunt , which can cause cyanosis even in the presence of adequate oxygen levels .

- Considering the options and the specific signs , the most likely diagnosis is Congenital heart anomaly with right-to-left shunt , as it can cause cyanosis and respiratory distress in a term infant .

- The other conditions are less likely given the specific signs and the absence of other supportive symptoms .

- The correct answer should be the one that best fits the clinical presentation and the mother's history .

- The most likely diagnosis is Congenital heart anomaly with right-to-left shunt .

- The question asks for the most likely diagnosis , and the options provided suggest that the correct answer is not explicitly listed .

- The closest match to the correct answer is D , as it is the only option that fits the clinical presentation and the mother's history .

- The other options are less likely given the specific signs and the absence of other supportive symptoms .

- The correct answer is D , as it is the most likely diagnosis given the clinical presentation and the mother's history .

- The most likely diagnosis is Congenital heart anomaly with right-to-left shunt .

- The correct answer is D .

</think>

<answer>D . Congenital heart anomaly with right-to-left shunt</answer>
