

Question:

A 17-year-old teenager is brought to the emergency department with severe bleeding from his right hand. He was involved in a gang fight about 30 minutes ago where he received a penetrating stab wound by a sharp knife in the region of the 'anatomical snuffbox'. A vascular surgeon is called in for consultation. Damage to which artery is most likely responsible for his excessive bleeding?

Answer Choices:

- A. Radial artery
- B. Ulnar artery
- C. Princeps pollicis artery
- D. Brachial artery

Reasoning + Answer:

`<think>` The anatomical snuffbox is a region on the dorsum of the hand, and injuries to this area often involve the radial artery, which passes through it. The brachial artery is too proximal and the ulnar and princeps pollicis arteries are less likely to be involved in such an injury. `</think>`
`<answer>`A. Radial artery`</answer>`
