

**Question:**

A 60-year-old woman is brought to the emergency department because of altered mental status for 2 hours. She and her husband were at the grocery store when she suddenly could not remember why she was there or how she got there. She has not had any head trauma. She has a history of depression and migraines. She does not smoke and drinks a glass of wine each night with dinner. She takes fluoxetine daily. She appears distressed and anxious. Her vital signs are within normal limits. She is fully alert and oriented to self and place but not to time. Every few minutes she asks how she got to the emergency department. She is able to follow commands and sustain attention. She recalls 3/3 objects immediately and recalls 0/3 objects at 5 minutes. The remainder of the neurological exam shows no abnormalities.

Which of the following is the most likely diagnosis?

Answer Choices:

- A. Transient global amnesia
- B. Depersonalization/derealization disorder
- C. Seizure
- D. Migraine

**Reasoning + Answer:**

<think> The patient presents with sudden onset of altered mental status, distress, and anxiety. She is fully alert and oriented to self and place but not to time, which suggests a time disorientation. She has a history of depression and migraines. Her neurological exam is normal, and she does not have a history of head trauma or seizures. Transient global amnesia is characterized by a sudden onset of confusion and disorientation to time, which is consistent with the patient's presentation. Depersonalization/derealization disorder involves a feeling of detachment from one's self or the environment, which is not the primary symptom in this case. A seizure would likely present with additional neurological deficits. Migraine can cause confusion, but the presentation is not typical for a migraine attack.

</think>

<answer>A. Transient global amnesia</answer>
