

Question:

Which of the following factors is associated with a decreased risk of Alzheimer's?

Answer Choices:

- A. Being African or Hispanic American
- B. A lower level of education
- C. Living in a city
- D. Being married
- E. Having a family history of Alzheimer's
- F. High intake of saturated fats
- G. Older age
- H. Eating fish
- I. Being a smoker
- J. Drinking alcohol regularly

Reasoning + Answer:

< reasoning process here >

To determine which factor is associated with a decreased risk of Alzheimer's , we analyze each option based on current medical and epidemiological evidence .

A . Being African or Hispanic American â Studies have shown that certain racial and ethnic groups , including African Americans and Hispanic Americans , may have higher risks of Alzheimer's due to socioeconomic , environmental , and genetic factors . So this is not protective .

B . A lower level of education â Lower educational attainment is associated with a higher risk of Alzheimer's , likely due to reduced cognitive reserve . So this increases risk , not decreases .

C . Living in a city â Urban living has mixed associations , but some studies suggest that city living may be linked to higher stress , pollution , and lifestyle risks , which may increase Alzheimer's risk . Not protective .

D . Being married â Multiple studies have shown that marital status can influence cognitive health . Being married is associated with better mental and physical health outcomes , including lower risk of dementia and Alzheimer's , possibly due to social support , reduced loneliness , and better health behaviors . This is a candidate for decreased risk .

E . Having a family history of Alzheimer's â Strong genetic predisposition ; increases risk , so not protective .

F . High intake of saturated fats â Associated with increased inflammation and cardiovascular disease , both risk factors for Alzheimer's . Increases risk .

G . Older age â Age is the biggest risk factor for Alzheimer's ; risk increases with age . So not protective .

H . Eating fish â Fish , especially fatty fish like salmon , are rich in omega - 3 fatty acids , which are linked to better brain health and reduced risk of neurodegenerative diseases . Evidence supports that fish consumption is associated with a lower risk of Alzheimer's .

I . Being a smoker â Smoking is a known risk factor for Alzheimer's due to neurotoxicity and vascular damage . Increases risk .

J . Drinking alcohol regularly â Excessive alcohol consumption increases risk , but moderate alcohol intake (especially red wine) has been linked to some protective effects due to antioxidants . However , "regularly" is ambiguous . Still , regular heavy drinking increases risk . So not protective .

Now , between D (being married) and H (eating fish) , both have some evidence of protective effects .

However , the strongest and most consistently supported factor among the options is eating fish due to omega - 3 fatty acids , which are directly linked to brain health and reduced neurodegeneration .

Thus , the most directly associated with decreased risk is H . Eating fish .

< answer > H </ answer >
