

Question:

In research study, a mother and her infant are alone in a room. A stranger enters and the mother leaves the room. When the mother returns to the room, the infant begins to cry and initially continues to do so even after being picked up by the mother. Eventually the infant settles down and returns to playing, apparently happily, with the toys provided. Which attachment classification is most likely to be appropriate for this infant

Answer Choices:

- A. Anxious avoidant
- B. Disorganized
- C. Disoriented
- D. Ambivalent
- E. Dependent
- F. Attachment disorder
- G. Fearful avoidant
- H. Avoidant
- I. Anxious resistant
- J. Secure

Reasoning + Answer:

<think>

- The infant's behavior suggests distress when the mother leaves and then a quick return to play when the mother returns , even if not immediately comforted .

- This pattern is characteristic of the anxious-resistant attachment style , where the child is highly dependent on the caregiver but also shows distress at separation and ambivalence upon reunion .

- Other attachment classifications like anxious-avoidant (showing no distress at separation and little comfort at reunion) or disorganized (showing confused or disoriented behavior) do not fit the described behavior .

- The behavior does not align with secure attachment , where the child is happy upon reunion , or avoidant attachment , where the child shows little distress at separation and little comfort upon reunion .

The most appropriate classification for this infant's behavior is :

I . Anxious resistant

</think>

<answer>I . Anxious resistant</answer>
