

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>
we know one glass costs 5 dollars so we can write that down
so we know 1 glass is 5 dollars so we can do 1 times 5 which equals 5 for the first glass
but then every second glass is 60 percent of the price so we know 60 percent is the same as doing 60 divided by 100 which equals 0 point 6
so we take the 5 dollar price and do 5 times 0 point 6 which equals 3 so now we know every second glass costs 3 dollars
now we know kylar wants 16 glasses so we know half of those will be the normal price and half will be the discount price
so we take the 16 glasses and split them in half so now we got 8 glasses at the normal price and 8 glasses at the discount price
so we take the 8 normal priced glasses and times them by the normal price which was 5 so 8 times 5 equals 40
then we take the 8 discount glasses and times them by the discount price which we worked out to be 3 so 8 times 3 equals 24
now we take the two lots of money we got 40 and 24 and do them both together so we do 40 plus 24 which equals 64
so now we know kylar has to pay 64 dollars for the 16 glasses
</think><answer>64</answer>
