

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think>
we know one glass costs 5 dollars so we can write that down
so we know 16 glasses at first might cost 16 times 5 which we can do the sum like this
so we do 16 times 5 which equals 80 so now we know the first 16 glasses would cost 80 dollars in total
if we didn't take the second bit into account
but the question tells us every second glass costs 60 percent of the normal price so we know the
second glass in each pair costs less
so we take the first glass cost of 5 dollars and do 60 percent of that to work out the second glass cost
so we do 5 dollars times 60 percent which we can do by changing the percent to a number by diving 60
by 100 to get 0 point 6
so now we do 5 times 0 point 6 which equals 3 so now we know the second glass in each pair costs 3
dollars
so now we know every second glass costs 3 dollars and we know there's 16 glasses so we know there
's 16 over 2 pairs of glasses because we know every second glass is half the number
so we do 16 divided by 2 which equals 8 so now we know there's 8 glasses at the cheaper price
so now we know 8 glasses at 3 dollars each so we do 8 times 3 which equals 24 so now we know the 8
cheaper glasses cost 24 dollars
so now we know the normal glasses cost 80 dollars and the cheaper ones cost 24 dollars so now we
know to work out the total cost we do both those amounts together
so we take the 80 dollars and add the 24 dollars together
80 plus 24 equals 104
so now we know kylar needs to pay 104 dollars for the 16 glasses
</think><answer> 104 </answer>
