

Question:

A 34-year-old woman presents to her OB/GYN with complaints of missing her last 3 periods as well as intermittent spontaneous milky-white nipple discharge bilaterally for the past 3 months. Vital signs are stable and within normal limits. Neurologic examination is without abnormality, including normal visual fields. Serology and MRI of the brain are ordered, with results pending. Which of the following sets of laboratory results would be expected in this patient?

Answer Choices:

- A. Decreased prolactin, decreased FSH, decreased LH
- B. Decreased prolactin, increased FSH, increased LH
- C. Increased prolactin, decreased FSH, increased LH
- D. Increased prolactin, decreased FSH, decreased LH

Reasoning + Answer:

<think> The patient is presenting with symptoms of amenorrhea and galactorrhea, which are common symptoms of hyperprolactinemia.

The patient's hormonal profile would likely show an increase in prolactin levels, which is consistent with option C.

Option A is incorrect because decreased prolactin levels do not align with the patient's symptoms.

Option B is incorrect because increased FSH and LH levels are more consistent with menopause or hypothalamic-pituitary-disconnection syndrome.

Option D is incorrect because decreased LH levels do not align with the patient's symptoms of amenorrhea.

Therefore, the correct answer is the option that shows increased prolactin levels. </think><answer> Increased prolactin, decreased FSH, increased LH </answer>
