

Question:

A 34-year-old poultry worker presents to his physician with a sore throat and a non-productive cough for 2 weeks. His cough is associated with fever. The vital signs include: blood pressure 120/80 mm Hg, heart rate 67/min, respiratory rate 18/min, and temperature 37.6°C (98.0°F). Physical examination shows oropharyngeal erythema and scattered, moist rales on lung auscultation. The patient’s X-ray demonstrates patchy reticular opacities in the perihilar regions of both lungs. After some additional tests, he is diagnosed with community-acquired pneumonia and is treated with cephalexin with modest improvement. Which of the following best describes the immune response elicited by the pathogen that is causing this patient’s condition?

Answer Choices:

- A. It activates TLR5 on the surface of macrophages.
- B. It primarily induces the Th1-cell response.
- C. Peptidoglycan is its major antigen that induces an immune response.
- D. This pathogen evades the immune response by encapsulation.

Reasoning + Answer:

<think> Given the presence of patchy reticular opacities and symptomsuding a potential bacterial infection, considering the inflammatory response and immune modulation associated with Th1 dominance in pneumonia contexts, evaluated the hallmark signs indicative of an encapsulated pathogen like Staphylococcus, leading to the conclusion about the immune response often involving Th1 response and epithelial evasion mechanisms including encapsulation.</think><answer> It primarily induces the Th1-cell response.</answer>
