

Question:

A 17-year-old teenager is brought to the emergency department with severe bleeding from his right hand. He was involved in a gang fight about 30 minutes ago where he received a penetrating stab wound by a sharp knife in the region of the ‘anatomical snuffbox’. A vascular surgeon is called in for consultation. Damage to which artery is most likely responsible for his excessive bleeding?

Answer Choices:

- A. Radial artery
- B. Ulnar artery
- C. Princeps pollicis artery
- D. Brachial artery

Reasoning + Answer:

<think>
the anatomical snuffbox region contain superficial palmar arch ; branch of palmar deep arch ; and the terminal branches of brachial artery
superficial palmar arch is supplied by superficial palmar arch anterior branch ; lateral anterior branch and terminal palmar branch .
brachial artery just distal to the anatomical snuffbox is territory of radial artery .
middle finger is supplied by the terminal palmar branch
the bleeding from the right side indicates ulnar artery
so the culprit is ulnar artery
</think>
<answer>B . Ulnar artery</answer>
