

Question:

A 34-year-old poultry worker presents to his physician with a sore throat and a non-productive cough for 2 weeks. His cough is associated with fever. The vital signs include: blood pressure 120/80 mm Hg, heart rate 67/min, respiratory rate 18/min, and temperature 37.6°C (98.0°F). Physical examination shows oropharyngeal erythema and scattered, moist rales on lung auscultation. The patient’s X-ray demonstrates patchy reticular opacities in the perihilar regions of both lungs. After some additional tests, he is diagnosed with community-acquired pneumonia and is treated with cephalexin with modest improvement. Which of the following best describes the immune response elicited by the pathogen that is causing this patient’s condition?

Answer Choices:

- A. It activates TLR5 on the surface of macrophages.
- B. It primarily induces the Th1-cell response.
- C. Peptidoglycan is its major antigen that induces an immune response.
- D. This pathogen evades the immune response by encapsulation.

Reasoning + Answer:

<think> The patient's symptoms and the presence of patchy reticular opacities in the perihilar regions of both lungs on X-ray suggest a bacterial infection , which is consistent with the diagnosis of community-acquired pneumonia and the use of cephalexin (an antibiotic) for treatment , which is effective against bacterial infections ; TLR5 activation and Th1 cell response are typically associated with bacterial infections and the immune system's response to them .</think>
<answer> B . It primarily induces the Th1-cell response . </answer>
