

Question:

A 34-year-old woman presents to her OB/GYN with complaints of missing her last 3 periods as well as intermittent spontaneous milky-white nipple discharge bilaterally for the past 3 months. Vital signs are stable and within normal limits. Neurologic examination is without abnormality, including normal visual fields. Serology and MRI of the brain are ordered, with results pending. Which of the following sets of laboratory results would be expected in this patient?

Answer Choices:

- A. Decreased prolactin, decreased FSH, decreased LH
- B. Decreased prolactin, increased FSH, increased LH
- C. Increased prolactin, decreased FSH, increased LH
- D. Increased prolactin, decreased FSH, decreased LH

Reasoning + Answer:

<think> The symptoms of missing periods and milky-white nipple discharge bilaterally are indicative of hyperprolactinemia, which can be caused by a pituitary adenoma that affects the production of follicle-stimulating hormone (FSH) and luteinizing hormone (LH), leading to a decrease in their levels as the body tries to regulate the hormone imbalance by reducing the stimulation of the pituitary gland, and prolactin levels would typically be increased as the adenoma may originate from the pituitary gland and cause an excess production of prolactin.</think>
<answer> D. Increased prolactin, decreased FSH, decreased LH </answer>
