

Question:

A 34-year-old woman presents to her OB/GYN with complaints of missing her last 3 periods as well as intermittent spontaneous milky-white nipple discharge bilaterally for the past 3 months. Vital signs are stable and within normal limits. Neurologic examination is without abnormality, including normal visual fields. Serology and MRI of the brain are ordered, with results pending. Which of the following sets of laboratory results would be expected in this patient?

Answer Choices:

- A. Decreased prolactin, decreased FSH, decreased LH
- B. Decreased prolactin, increased FSH, increased LH
- C. Increased prolactin, decreased FSH, increased LH
- D. Increased prolactin, decreased FSH, decreased LH

Reasoning + Answer:

<think> The patient has galactorrhea and amenorrhea which is a sign of hyperprolactinemia and this will cause a decrease in the fsh and lh test in the adrenal reserve and the low fsh and lh will cause the pituitary to increase prolactin production and the prolactin will remain high even after suppressing the fsh and lh so the lab results will show increased prolactin with decreased fsh and lh

</think>

<answer> D . Increased prolactin , decreased FSH , decreased LH </answer>
