

Question:

A 34-year-old woman presents to her OB/GYN with complaints of missing her last 3 periods as well as intermittent spontaneous milky-white nipple discharge bilaterally for the past 3 months. Vital signs are stable and within normal limits. Neurologic examination is without abnormality, including normal visual fields. Serology and MRI of the brain are ordered, with results pending. Which of the following sets of laboratory results would be expected in this patient?

Answer Choices:

- A. Decreased prolactin, decreased FSH, decreased LH
- B. Decreased prolactin, increased FSH, increased LH
- C. Increased prolactin, decreased FSH, increased LH
- D. Increased prolactin, decreased FSH, decreased LH

Reasoning + Answer:

<think> The patient has hyperprolactinemia from a pituitary adenoma and this will cause a decrease in the fsh and lh levels and the high prolactin will cause hyperpituitarism and an enlarged pituitary gland on the MRI and low fsh and lh will cause the ovaries to stop producing estrogen and cause the woman to miss her periods and produce milk from her nipples even though she is not nursing or pregnant </think>

<answer> A. Decreased prolactin, decreased FSH, decreased LH </answer>
