

Question:

A 34-year-old poultry worker presents to his physician with a sore throat and a non-productive cough for 2 weeks. His cough is associated with fever. The vital signs include: blood pressure 120/80 mm Hg, heart rate 67/min, respiratory rate 18/min, and temperature 37.6°C (98.0°F). Physical examination shows oropharyngeal erythema and scattered, moist rales on lung auscultation. The patient’s X-ray demonstrates patchy reticular opacities in the perihilar regions of both lungs. After some additional tests, he is diagnosed with community-acquired pneumonia and is treated with cephalexin with modest improvement. Which of the following best describes the immune response elicited by the pathogen that is causing this patient’s condition?

Answer Choices:

- A. It activates TLR5 on the surface of macrophages.
- B. It primarily induces the Th1-cell response.
- C. Peptidoglycan is its major antigen that induces an immune response.
- D. This pathogen evades the immune response by encapsulation.

Reasoning + Answer:

<think>
To approach this reasoning problem , we need to analyze the context of the question , which is centered around the immune response to a specific type of pathogen causing community-acquired pneumonia . The correct answer must directly address this immune response in the context of bacterial infections , which is best represented by the option that mentions peptidoglycan , a component of bacterial cell walls . This directly correlates with the pathogen causing pneumonia , which is often bacterial . Therefore , the most appropriate answer is "Peptidoglycan is its major antigen that induces an immune response ."</think>

<answer>
Peptidoglycan is its major antigen that induces an immune response .
