

Question:

Mack wants to count things and decided to count how many birds there are in the sky over the next week. On days one and two, Mack saw a total of 50 birds. On day three he saw none. On days four and five, he saw 120 birds. On day six he saw 20 and on day seven he saw 90. On average, how many birds did Mack see in a day?

Reasoning + Answer:

<think> Mack wants to calculate the average number of birds she saw in a day. So, first she has to find out total number of birds she saw in seven days. On days one and two, he saw 50 birds, so total birds still now is $50 + 50 = 100$. On day three, he saw none, so total birds now becomes $100 + 0 = 100$. On days four and five, he saw 120 birds, so total birds now is $100 + 120 = 220$. On day six, he saw 20 birds, so total birds now is $220 + 20 = 240$. On day seven, he saw 90 birds, so total birds now is $240 + 90 = 330$. Now, to find out average number of birds she saw in a day, he will divide total birds by number of days. So, average number of birds Mack saw in a day is $330 / 7 = 47.14$. Therefore, Mack saw approximately 47.14 birds in a day. </think><answer>47.14</answer>
