

Question:

Julia's boat sprang a leak while she was out on the lake. The boat was taking on two liters of water for every ten feet she rowed back towards shore. It took her sixteen seconds to row twenty feet. The shore was 64 seconds away. How much water had the boat taken on by the time Julia reached shore?

Reasoning + Answer:

<think>the boat is taking on 2 liters of water for every 10 feet it rows, so the rate of taking water is $2 / 10 = 0.2$ liters per foot, it took 16 seconds to row 20 feet, so the time taken to row 64 feet is $64 * 16 / 20 = 51.2$ seconds, the amount of water taken on in 51.2 seconds is $0.2 * 51.2 = 10.24$ liters</think><answer> 10.24</answer>
