

Question:

Mark buys one lottery ticket with a 20% chance of winning and a second lottery ticket that's three times more likely to win. What is the probability, expressed as a percentage, that both tickets are winners?

Reasoning + Answer:

<think>The probability of the first ticket being a winner is 20%, or 0.2
The second ticket is three times more likely to win, so its probability of being a winner is 3 Ã 20% = 60%, or 0.6
To find the probability that both tickets are winners, we multiply their individual probabilities: 0.2 Ã 0.6 = 0.12
Converting this to a percentage, the probability that both tickets are winners is 12%
</think><answer>12</answer>
