

Question:

Two girls each got $\frac{1}{6}$ of the 24 liters of water. Then a boy got 6 liters of water. How many liters of water were left?

Reasoning + Answer:

<think> we know there's 24 litres of water to start with so we can write that down then we know two girls each got $\frac{1}{6}$ of the water so we can do the sum to work out how much water that is so we take the 24 litres and do $24 \div 6$ because the question says each girl got $\frac{1}{6}$ so we do the sum $24 \div 6$ which equals 4 so now we know each girl got 4 litres so now we know the girls together got 4 litres each so we do another sum to work out how much the girls got in total we take the 4 litres each girl got and do them both so we do $4 + 4$ which equals 8 so now we know the girls together got 8 litres so now we know the girls together got 8 litres so we can do a sum to work out how much is left we take the total amount of water which was 24 litres and take away the 8 litres the girls got so we do $24 - 8$ $24 - 8$ equals 16 but the question also says a boy got 6 litres so we need to take those 6 litres away from the 16 we just worked out so we take the 16 litres left and take away the 6 the boy got so we do $16 - 6$ $16 - 6$ equals 10 so now we know how many litres are left </think>
><answer> 10 </answer>
