

Question:

A 14 year old boy with difficulty in walking and behavioural disturbance, recovered from prolonged jaundice recently, has bluish pigmentation over lunula. The next investigation to be done: Answer Choices: A. Nail fold cappillaroscopy B. Slit lamp examination C. Biopsy of the pigmented area D. Ankle-brachial pressure index

Reasoning + Answer:

<think> The patient is a 14-year-old boy with a history of prolonged jaundice and difficulty in walking, along with behavioural disturbances. The bluish pigmentation over the lunula suggests a possible diagnosis of Wilson's disease, a genetic disorder that leads to copper accumulation in the body, causing liver and brain symptoms. The bluish pigmentation over the lunula is a classic sign of Wilson's disease. The most appropriate next investigation would be a slit lamp examination to look for the Kayser-Fleisch rings, which are a hallmark of Wilson's disease. This involves examining the eyes for the presence of these rings, which are due to copper deposition. </think> <answer> B. Slit lamp examination </answer>
