

Question:

Which of the following is true about Constitutional Delay in growth? Answer Choices: A. Neonates with constitutional delay show anomalies at birth B. IGF-1 levels are low for chronological age C. Bone age is normal D. IGF-1 levels are low for bone age

Reasoning + Answer:

<think>Constitutional delay in growth is a condition where children grow at a slower rate than their peers, but eventually catch up. It is also known as constitutional growth delay. In this condition, the children are born with a lower height percentile, but their bone age is also delayed, meaning that their bones are not mature for their chronological age. IGF-1 (Insulin-like Growth Factor 1) levels are typically appropriate for the child's bone age, not their chronological age. This means that in children with constitutional delay in growth, IGF-1 levels are usually normal or low for their bone age, not their chronological age. The children with constitutional delay in growth do not have any birth anomalies, so option A is not correct. </think><answer>D. IGF-1 levels are low for bone age</answer>
