

Question:

A 2-day-old newborn boy has failed to pass meconium after 48 hours. There is an absence of stool in the rectal vault. Family history is significant for MEN2A syndrome. Which of the following confirms the diagnosis? Answer Choices: A. Absence of ganglion cells demonstrated by rectal suction biopsy B. Atrophic nerve fibers and decreased acetylcholinesterase activity C. Barium enema demonstrating absence of a transition zone D. Rectal manometry demonstrating relaxation of the internal anal sphincter with distension of the rectum

Reasoning + Answer:

<think> Given the newborn's history indicative of MEN2A syndrome, along with the absence of meconium indicative of potential rectal sphincter issues, suggesting a need for exploratory procedures to assess the rectal functionality and nerve fiber presence. </think> <answer> Absence of ganglion cells demonstrated by rectal suction biopsy </answer>
