

**Question:**

A 42-year-old homeless man is brought to the emergency room after he was found unconscious in a park. He has alcohol on his breath and is known to have a history of chronic alcoholism. A noncontrast CT scan of the head is normal. The patient is treated for acute alcohol intoxication and admitted to the hospital. The next day, the patient demands to be released. His vital signs are a pulse 120/min, a respiratory rate 22/min, and blood pressure 136/88 mm Hg. On physical examination, the patient is confused, agitated, and sweating profusely, particularly from his palms. Generalized pallor is present. What is the mechanism of action of the drug recommended to treat this patient's most likely condition? Answer Choices: A. It increases the duration of GABA-gated chloride channel opening. B. It increases the frequency of GABA-gated chloride channel opening. C. It decreases the frequency of GABA-gated chloride channel opening. D. It decreases the duration of GABA-gated chloride channel opening.

**Reasoning + Answer:**

<think> Given the patient's history of alcohol intoxication leading to confusion and agitation, interventions often included drugs that counteract the enhanced GABA effect to restore normal neural activity. </think> <answer> It increases the frequency of GABA-gated chloride channel opening. </answer>
