

Question:

A 55-year-old man presents to his primary care physician for a regular check-up. The patient was born in Germany in 1960 in with shortened limbs, underdeveloped digits, absent external ears, and a cleft palate. He is currently in a wheelchair. His past medical history is also notable for hypertension and allergies. He takes lisinopril daily and loratadine as needed. His mother had a complicated past medical history and took multiple medications during her pregnancy. His temperature is 98.6°F (37°C), blood pressure is 120/80 mmHg, pulse is 90/min, and respirations are 20/min. The drug that most likely caused this patient's condition is also indicated for which of the following? Answer Choices: A. Acne vulgaris B. Deep venous thrombosis C. Multiple myeloma D. Recurrent miscarriage

Reasoning + Answer:

<think> Given the historical markers including cleft palate, limb shortening, and maternal use of drugs during gestation, suggesting teratogenic effects, coupled with lisinopril's known risks, leading towards considering its potential link to such congenital anomalies. </think> <answer> Deep venous thrombosis </answer>
