

Question:

The MOST likely site of lesion in a patient with Wernicke's hemianopic pupil is: Answer Choices: A. Optic nerve B. Optic tract C. Optic chiasma D. Optic radiation

Reasoning + Answer:

<think> The lesion in Wernicke's syndrome that causes homonymous hemianopia is in the optic chiasma and because it is a homonymous hemianopia the part of the chiasma that is affected is the part that receives the visual information from the nasal half of the retina from the opposite eyes and this results in a homonymous hemianopic visual field defect in the temporal side of each eye </think> <answer> C . Optic chiasma </answer>
