

Question:

A 77-year-old man presents to his primary care physician with lightheadedness and a feeling that he is going to "pass out". He has a history of hypertension that is treated with captopril. In the office, his temperature is 38.3°C (100.9°F), the pulse is 65/min, and the respiratory rate is 19/min. His sitting blood pressure is 133/91 mm Hg. Additionally, his supine blood pressure is 134/92 mm Hg and standing blood pressure is 127/88 mm Hg. These are similar to his baseline blood pressure measured during previous visits. An ECG rhythm strip is obtained in the office. Of the following, what is the likely cause of his presyncope? Answer Choices: A. Captopril B. Hypertension C. Left bundle branch block D. Right bundle branch block

Reasoning + Answer:

<think> The patient's orthostatic hypotension and the fact that he is on an angiotensin converting enzyme inhibitor which can cause orthostatic hypotension and lightheadedness and presyncope and syncope episodes is due to the side effect of the captopril he is taking and the drop in blood pressure when standing up </think> <answer> A . Captopril </answer>
