

Question:

A 32-year-old G2P0A1 woman presents at 36 weeks of gestation for the first time during her pregnancy. The patient has no complaints, currently. However, her past medical history reveals seizure disorder, which is under control with valproic acid and lithium. She has not seen her neurologist during the past 2 years, in the absence of any complaints. She also reports a previous history of elective abortion. The physical examination is insignificant. Her blood pressure is 130/75 mm Hg and pulse is 80/min. The patient is scheduled to undergo regular laboratory tests and abdominal ultrasound. Given her past medical history, which of the following conditions is her fetus most likely going to develop? Answer Choices: A. Trisomy 21 B. Neural tube defects (NTDs) C. Intrauterine growth restriction D. Limb anomalies

Reasoning + Answer:

<think> To approach this reasoning problem, we need to analyze the context of the question, which is centered around identifying a potential fetal condition based on a mother's medical history, specifically related to a seizure disorder treated with valproic acid. From the given options, the most relevant and medically accurate answer is "Neural tube defects (NTDs)," which is a well-documented side effect of valproic acid used during pregnancy. This directly correlates with the pharmaceutical and medical scenario presented in the question. </think> <answer> Neural tube defects (NTDs) </answer>
