

Question:

A 17-year-old teenager is brought to the emergency department with severe bleeding from his right hand. He was involved in a gang fight about 30 minutes ago where he received a penetrating stab wound by a sharp knife in the region of the ‘anatomical snuffbox’. A vascular surgeon is called in for consultation. Damage to which artery is most likely responsible for his excessive bleeding? Answer Choices: A. Radial artery B. Ulnar artery C. Princeps pollicis artery D. Brachial artery

Reasoning + Answer:

<think> Given that the wound specifically targets the anatomical snuffbox, implying potential injury to vessels crucial for finger circulation, considering the anatomical relevance, the brachial artery, supplying the arm including wrist and hand regions, stands out as a pivotal artery susceptible to such injury leading to severe bleeding. </think> <answer> Brachial artery </answer>
