

Question:

Kylar went to the store to buy glasses for his new apartment. One glass costs \$5, but every second glass costs only 60% of the price. Kylar wants to buy 16 glasses. How much does he need to pay for them?

Reasoning + Answer:

<think> Let's start by calculating the cost of the first and every second glass . The first glass costs \$ 5 . For each second glass , Kylar pays only 6 0 % of the price of the first glass .

So , the price for every second glass is $\text{\textbackslash}(0.60 \text{\textbackslash} \times 5 = 3 \text{\textbackslash})$ dollars .

Kylar wants to buy 1 6 glasses . Let's consider how they are priced . The pattern suggests that the glasses can be grouped in pairs : (1 st glass , 2 nd glass) , (3 rd glass , 4 th glass) , and so on . Each of these pairs contains one glass at \$ 5 and one glass at \$ 3 .

There are 1 6 glasses , which includes 8 such pairs (since each pair contains 2 glasses) .

Let's calculate the total cost :

- The first glass from each pair costs \$ 5 , and we have 8 glasses of this type at \$ 5 each , so the total cost for these glasses is $\text{\textbackslash}(8 \text{\textbackslash} \times 5 = 40 \text{\textbackslash})$ dollars .

- The second glass from each pair costs \$ 3 , and we have 8 glasses of this type at \$ 3 each , so the total cost for these glasses is $\text{\textbackslash}(8 \text{\textbackslash} \times 3 = 24 \text{\textbackslash})$ dollars .

Adding these together , the total cost is $\text{\textbackslash}(40 + 24 = 64 \text{\textbackslash})$ dollars . </think>

<answer> 6 4 </answer>
